Part I

Coxeter groups

1

Introduction

This chapter is based on the first chapter of [MKS04]. This chapter will be an introduction of what groups are and how they are generated.

We recall in group theory that a group $(G, \cdot)$ is a non-empty set G of elements with a binary operation $\cdot$ for which the next axioms are satisfied:

- **Closure:** For all $a, b \in G$, c such that $a \cdot b = c$ implies that $c \in G$.
- **Associativity:** The operation $\cdot$ is associative, which means that for any elements $a, b, c \in G$:
$$(ab)c = a(bc)$$
- **Identity element:** There exists an element of G noted 1 for which:
$$a \cdot 1 = 1 \cdot a = a$$
- **Inverse element:** For any $a \in G$ there exists an *element* a^{-1} for which:
$$a \cdot a^{-1} = a^{-1} \cdot a = 1$$

We know two ways of defining a group; defining a *symmetry* of a set and if it is presented by generators and relators.

1.1 Symmetric groups

Definition 1.1 (Symmetric group). *The symmetric group on the set G is the group whose elements are permutations of the elements of G and its operation is the permutation composition. If $G = \{1, \ldots, n$ we call it S_n. [Sag01].*

Proposition 1.2. *S_n has order $n!$ and every group G of order n is a subgroup of S_n.*

1.1.1 Permutations

Now that we know what symmetric groups are, we know that it's mainly based in permutations. In this subsection we define every operation on permutations used in these groups.

Definition 1.3 (Two-line notation). *Given $i \in \{1, \dots, n\}$ and π the permutation function we represent a permutation listing every elements of the set in two lines where in the first line we have the elements and the second one its image in the π function:*

$$\begin{pmatrix} 1 & 2 & 3 & 4 & 5 & \dots & i \\ \pi(1) & \pi(2) & \pi(3) & \pi(4) & \pi(5) & & \pi(i) \end{pmatrix} \tag{1.1}$$

Definition 1.4 (Cycle notation). *Given $i \in \{1, \dots, n\}$ and π the permutation function, the elements of the sequence $i, \pi(i), \pi^2(i), \dots$ cannot be distinct. Taking the power p such that $\pi^p(i) = i$, we can note the permutation as the cycle:*

$$(i, \pi(i), \pi^2(i), \dots, \pi^{p-1}(i)) \tag{1.2}$$

Which means that given a cycle (i, j, k), the element i is send to j, j is sent to k and k is sent to i, cyclically, e.g. the permutation 23145 of $n = \{1, 2, 3, 4, 5\}$ can be written with cycle notation as $(1, 2, 3)(4)(5)$. Remark that every element of the set has to be used.

1.2 Presentation of groups

In this section we show how a group can be defined by generators and relators:

Definition 1.5. *A group can be defined by:*

$$Gr \cong \langle G | R \rangle \tag{1.3}$$

being $G = \{a, b, c, \dots\}$ the set of generators *and $R = \{A, B, C, \dots\}$ the set of* relators *or* relations *such that every $X \in R$ is a word in $(G \cup G^{-1})^*$ such that $X = 1$.*

For example, the dihedral group D_n has the next presentation where q is a rotation and r a reflection:

$$D_n \cong \langle \{q, r\} | \{r^2, q^n, rqrq\} \rangle$$

2

Coxeter groups

In this chapter, we explain the interest and motivation of coxeter groups by analysing a symmetric group. The main example of this chapter will be the symmetric group S_3. This group can be defined in three ways.

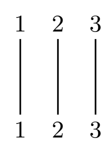

Fig. 2.1. The wiring diagram for the permutation 123.

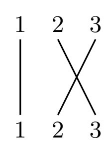

Fig. 2.2. The wiring diagram for the permutation 132.

- Combinatorial: Given a cyclic noted permutation we can represent it as a *wiring diagram.*
  For example, for the permutation 123 we have the following wire diagram:
- Algebraic: Presentation of groups as seen in section 1.2.

$$S_3 \cong \langle \{s_1, s_2\} | s_1 s_2 s_1 = s_2 s_1 s_2, s_1^2 = e, s_2^2 = e, \\ (s_1 s_2)^3 = s_1 s_2 s_1 s_2 s_1 s_2 = e\} \rangle \tag{2.1}$$

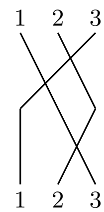

Fig. 2.3. The wiring diagram for the permutation composition $132 \circ 231$.

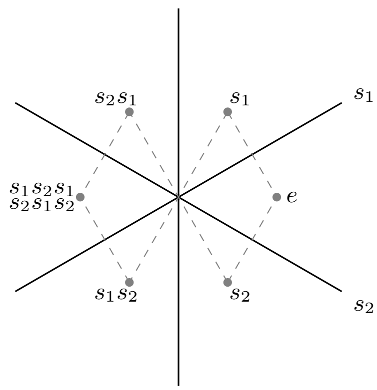

Fig. 2.4. Geometrical representation of S_3. The grey dotted lines represent the reflection applied between two points.

- Geometrical: We can represent geometrically a coxeter group by reflections. In figure 2.4 you can see a geometrical representation of S_3 where s_1 and s_2 are the generators of S_3 and also reflections on the plane.
  If you see the figure you can remark that $s_1s_2s_1 = s_2s_1s_2$, $s_1^2 = e$ and s_2^2; S_3 is a coxeter group.

2.1 Coxeter groups

In this section we define the mathematical objects that represent coxeter groups. S being a finite set:

Definition 2.1. *A* coxeter matrix $m : S \times S \to \{1, 2, \ldots, \infty\}$ *such that:*

1. $m(s, s') = 1 \;\; \forall s \in S$
2. $m(s, s') = m(s', s) \;\; \forall s \in S$
3. $m(s, s') > 1 \quad$ *if* $s \neq s'$

Definition 2.2. *A* coxeter diagram *is a graph where the set of vertices are the elements of* S *and the labelled edges are such that:*

1. if $m(s,s') = 2$*:* 
2. if $m(s,s') = 3$*:* 
3. if $m(s,s') \geq 4$*:* 
where the label of the edge is $m(s,s')$*.*

where m *is the coxeter matrix.*

Example 2.3. If we have a coxeter matrix m:

$$m = \begin{bmatrix} 1 & 3 & 2 \\ 3 & 1 & 4 \\ 2 & 4 & 1 \end{bmatrix} \tag{2.2}$$

where the line or column i corresponds to the generator s_i of the coxeter group. Then the related coxeter diagram can be drawn like this:

Given the definition of m, we can now define formally a coxeter group.

Definition 2.4. *A* coxeter group *is a group with the following presentation:*

$$\langle S \mid (s,s')^{m(s,s')} = e, \forall s,s' \in S\}\rangle \tag{2.3}$$

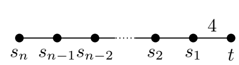
where S *si a group and* m *the coxeter matrix with* $m(s,s') < \infty$*.*

Example 2.5. The symmetric group S_n can be represented with the following coxeter diagram:

because for every $i < n$, we have that $s_i s_{i+1} s_i s_{i+1} = e$, so $(s_i s_{i+1})^2 = e$, which means that $m(s_i, s_{i+1}) = 2$ for every $i < n$.

Definition 2.6. *The tuple* (W,S) *is a coxeter system where* W *is a coxeter group and* S *a group of generators.*

We introduce the hyperoctahedral group S_n^B being the group of signed permutations of $[n] := \{1,2,\ldots,n\}$. The group set is $\{1,2,\ldots,m,\bar{1},\bar{2},\ldots,\bar{n}\}$. We have a new generator t, that will change the sign of an element. In figure 2.1 you can see an example of permutations withing this group. This is a coxeter group and its diagram is:



Given a coxeter system (W,S), we can then define $T := \{wsw^{-1} \mid s \in S, w \in W\} \subseteq W$ where s are simple reflections. Now we can define π.

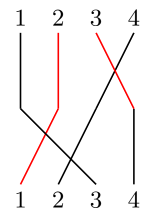


Fig. 2.5. The wiring diagram for the permutation $3\bar{1}24 \circ 1\bar{2}\bar{4}3$. You can see that there is a permutation that changes its sign two times.

Definition 2.7. *Given $W \to S_T^B$ and $w \to \pi_w$ with $t \in T$ and $s \in S$:*

$$\pi_s(t) := \begin{cases} -s & \textit{if } t = s \\ sts & \textit{if } t \neq s \end{cases} \tag{2.4}$$

This application is a bijection because its inverse is itself ($\pi_s(\pi_s(s)) = s$):

$$\pi(\pi_s(t)) = \begin{cases} \pi_s(-s) & \text{if } t = s \\ \pi_s(tsts) & \text{if } t \neq s \end{cases} \tag{2.5}$$

We clearly see that $\pi_s(sts) = s(sts)s = t$ and $\pi_s(-s) = -\pi_s(s) = -s$.

Theorem 2.8. *The application π that we defined on the set of generators S of the coxeter System (W, S), extend uniquely to an injective homomorphism $\pi : W \to S_T^B$*

Proof. First of all, we need to show that the extension of π is well defined. It was clear, due to the definition of π on S that for every $s \in S$, the application $\pi_s \in S_T^B$. Indeed, for every $t \in T$ we had that $\pi_s(t) \in T \cup \overline{T}$ and we had that π_s defined a bijection on $T \cup \overline{T}$. Now, we need to check that its extension on all of W is still well defined. We need to check 2 things. First, we need to check that $\forall w \in W$ the application $\pi_w \in S_T^B$. But, since we extended π from S to W to be a group morphism, we know that π_w is by definition the composition of π_s for some $s \in S$ and thus is an element of S_T^B. Secondly, we need to check that this application π_w doesn't depend on the writing of $w \in W$. To this aim, let's take $t \in T$ and let $w = s_1 s_2 .. s_k$ for some $s_i \in S$ (this is the form of every element of W since $s_i = s_i^{-1}$ for all i). Since, we want π to be a homomorphism, we have that :

$$\begin{aligned}
\pi_w(t) &= \pi_{s_1} \circ \pi_{s_2} \circ ... \circ \pi_{s_k}(t) \\
&= \pi_{s_1} \circ \pi_{s_2} \circ ... \circ \pi_{s_{k-1}}(\pm s_k t s_k) \\
&\quad \text{(with } - \text{ iff } s_k t s_k = s_k \iff t = s_k) \\
&= \pi_{s_1} \circ \pi_{s_2} \circ ... \circ \pi_{s_{k-2}}(\pm \pm s_{k-1} s_k t s_k s_{k-1}) \\
&\quad \text{(with } - \text{ iff } s_{k-1} s_k t s_k s_{k-1} = s_{k-1} \iff t = s_k s_{k-1} s_k) \\
&= \pi_{s_1} \circ \pi_{s_2} \circ ... \circ \pi_{s_{k-3}}(\pm \pm \pm s_{k-2} s_{k-1} s_k t s_k s_{k-1} s_{k-2}) \\
&\quad \text{(with } - \text{ iff } s_{k-1} s_k t s_k s_{k-1} = s_{k-1} s_{k-2} \iff t = s_k s_{k-1} s_{k-2} s_{k-1} s_k) \\
&= \quad \vdots \quad \vdots \quad \vdots \quad \vdots \quad \vdots \quad \vdots \quad \vdots \quad \vdots \quad \vdots \\
&= \pm \pm \cdots \pm s_1 s_2 ... s_k t s_k s_{k-1} ... s_1 \\
&\quad \text{(with } - \text{ iff } s_1 ... s_{k-1} s_k t s_k s_{k-1} ... s_1 = s_1 \iff t = s_k ... s_2 s_1 s_2 ... s_k) \\
&= \mathrm{sgn}_w(t)\ wtw^{-1}
\end{aligned} \tag{2.6}$$

Where the function $\mathrm{sgn}_w(t)$ is a sign function counting the number of times we and an index $l \in \{1, 2, ...k\}$ such that $t = s_k ... s_{l-1} s_l s_{l-1} ... s_k$. Namely :

$$\mathrm{sgn}_w(t) \;=\; (-1)^{\#\{1 \le l \le k \,:\, t = s_k ... s_{l-1} s_l s_{l-1} ... s_k\}} \tag{2.7}$$

As we will show just after this sign function doesn't depend of the writing of $w \in W$ in the coxeter system (W, S). But first, let us get some intuition about what this sign function is counting, by looking to the case of S_n : aaaaaaaaaaa

We are now going to use equation 2.6 to prove that π is a well defined homomorphism which is equivalent to show that the sign function doesn't depend on the writing of $w \in W$ in the Coxeter system (W, S). It suffice to show that all the relations we had in (W, S) are satisfied by their image in S_T^B. I.e. let's take $s, s' \in S$ we want to show that :

$$(\pi_s \circ \pi_{s'})^{m(s,s')} \;=\; \mathrm{Id}_{S_T^B} \tag{2.8}$$

Since $(ss')^{-1} = s's$, equation 2.6 gives for all $t \in T$:

$$(\pi_s \circ \pi_{s'})^{m(s,s')}(t) \;=\; \pm\; (ss')^{m(s,s')} t (s's)^{m(s,s')} \;=\; \pm\; ete \;=\; \pm\; t \tag{2.9}$$

But the sign must be $+$ as here, $w = (ss')^{m(s,s')}$ and therefore we look at :

$$\#\{1 \le l \le m(s,s') \;:\; t = \underbrace{s'ss'...s'ss'}_{2l-1 \text{ characters}}\ \} \tag{2.10}$$

Which must be even. Indeed, if for some $l \le m(s,s')/2$ we have :

- if $m(s, s')$ is even :

$$t \;=\; \underbrace{s'ss'...s'ss'}_{2l-1 \text{ characters}} \;=\; \underbrace{s'ss'...s'ss'}_{2l-1+m(s,s') \text{ characters}} \;=\; \underbrace{s'ss'...s'ss'}_{2(l+m(s,s')/2)-1 \text{ characters}} \tag{2.11}$$

- if $m(s,s')$ is odd :

$$t \;=\; \underbrace{s'ss'...s'ss'}_{2l-1 \text{ characters}} \;=\; \underbrace{s'ss'...s'ss'}_{2l-1+m(s,s') \text{ characters}} \;=\; \underbrace{s'ss'...s'ss'}_{2((m(s,s')-1)/2+l)+1 \text{ characters}} \tag{2.12}$$

Which shows that if one index is counted below $m(s,s')/2$ then there exists an other index counted strictly upper than $m(s,s')/2$ and vis versa. Thus the set must be even and the sign must be $+$. Therefore, equation (2.8), is proved and we π is a well defined morphism.

It last to show that the extension of π is injective. Let $u, v \in W$ be such that $\pi_u = \pi_v$ then, we have that :

$$\pi_{uv^{-1}} \;=\; \pi_u \circ \pi_{v^{-1}} \;=\; \mathrm{Id}_{S_T^B} \;=\; \pi_e \tag{2.13}$$

Thus, we just need to show that if $w \in W$ is such that $\pi_w = \pi_e$ then $w = e$ to prove the injectivity of π. Now, let's take $w \in W$ such that $\pi_w = \pi_e$ and let's suppose absurdly that $w \neq e$ then, there exists $k \geq 1$ such that $w = s_1...s_k$ is the shorter way possible to write $w \in W$ then (meaning that k is the smallest possible) :

$$\begin{aligned} s_k \;&=\; \pi_e(s_k) \;=\; \pi_w(s_k) \;=\; \mathrm{sgn}_w(s_k)\ s_1...s_{k-1}s_k s_k s_k s_{k-1}...s_1 \\ &=\; \mathrm{sgn}_w(s_k)\ s_1...s_{k-1}s_k s_{k-1}...s_1 \end{aligned} \tag{2.14}$$

But $\mathrm{sgn}_w(s_k) = -1$ because :

$$\{1 \leq l \leq k \ : \ t = s_k...s_{l-1}s_l s_{l-1}...s_k\} \;=\; \{k\} \tag{2.15}$$

Indeed, for $l = k$ we have $s_k = s_k$. But if $l \neq k$ and if we had :

$$s_k = \; s_k..s_l..s_k \tag{2.16}$$

Then we would have :

$$s_{l-1}...s_k s_k \;=\; s_l...s_k \tag{2.17}$$

And therefore we would have a contradiction with the minimality of k since :

$$\begin{aligned} w &= s_1...s_l s_{l-1} s_l...s_k \\ &= \; s_1...s_{l-1}s_{l-1}...s_k s_k \\ &= \; s_1..s_{l-2}s_{l+1}...s_{k-1} \\ &= \; s_1...s_{l-2}s_{l+11}...s_{k-1} \end{aligned} \tag{2.18}$$

which is a shorter way to write w. Therefore, we have that $\mathrm{sgn}_w(s_k) = -1$ and thus equation 2.14 gives :

$$s_k \;=\; - \; s_1...s_{k-1}s_k s_{k-1}...s_1 \tag{2.19}$$

Which is a contradiction due to the presence of a sign. $\square$

We are now going to define the notions of **parity** and **length** of an element in a Coxeter group.

Definition 2.9. *Let (W, S) be a coxeter system, and let $w \in W$, then we say that $w = s_1...s_k$ $(s_l \in S)$ is :*

- ***even*** *when k is even.*
- ***odd*** *when k is odd.*

*This is what we call the **parity** of $w \in W$.*

Remark 2.10. As all the relations of a Coxeter group involve a pair number of $s \in S$ we see that the parity of an element $w \in W$ doesn't depend on its writing in W.

The set of even elements of a Coxeter system (W, S) is a subgroup of W called the **alternating** subgroup.

Remark 2.11. When S_n is seen as a Coxeter group with $S = \{s_1...s_{n-1}\}$ and the Coxeter matrix $m(s_i, s_{i+1}) = 3$ and $m(s, s') = 2$ for every other couple $()s, s') \neq (s, s)$ see that the two notions of alternating group does coincide.

Definition 2.12. *Let (W, S) be a Coxeter system, the **length** $l(w)$ of an element $w \in W$ is defined as the smallest integer $k \in \mathbb{N}$ such that there exists $s_1, ..., s_k \in S$ with $w = s_1...s_k$.*

The purpose of what follows is to prove the following theorem :

Theorem 2.13. *Let (W, S) be a Coxeter system, and let $w \in W$ then :*

$$l(w) \ = \ \#\{t \in T \ : \ sgn_{w^{-1}}(t) = -1\} \tag{2.20}$$

Example 2.14. In the case where $W = S_n$ with the common representation, $l(w)$ is exactly the number of inversion of w^{-1} which is exactly the same as the number of inversion of w itself.

Before proving this thorem, we focus our attention on some lemma :

Lemma 2.15. *Let (W, S) be a Coxeter system and let $w \in W$, $t \in T$ then :*

$$sgn_{w^{-1}}(t) = -1 \quad \Longleftrightarrow \quad l(tw) \ < \ l(w) \tag{2.21}$$

Proof. Let's suppose that $\mathrm{sgn}_{w^{-1}}(t) = -1$ and let $w = s_1...s_k$ with $k = l(w)$ then $w^{-1} = s_k...s_1$. We know that there must exists some $1 \leq l \leq k$ such that $t = s_1...s_l..s_1$ but then :

$$\begin{aligned} tw \ &= \ s_1 s_2 ... s_l ... s_1 \ q_1 s_2 ... s_l s_{l+1} ... s_k \\ &= \ s_1 s_2 ... s_{l-1} s_{l+1} ... s_k \\ &= \ s_1 s_2 ... \hat{s}_l ... s_k \end{aligned} \tag{2.22}$$

From which we conclude that $l(tw) \leq k-1 \ < \ k = l(w)$ and the first implication is proven.
Conversely, let's suppose that $l(tw) < l(w)$ then, as $tt = e$ we have that :

$$l(tw) \ < \ l(ttw) \ \Rightarrow l(ttw) \not< l(tw) \tag{2.23}$$

Therefore, the first implication that we already proved, gives us by taking $w \tilde{=} tw$ that :

$$\mathrm{sgn}_{w^{-1}t}(t) = +1 \tag{2.24}$$

Thus,

$$\pi_{(tw)^{-1}}(t) \ = \ +1 \ (tw)^{-1} \ t \ (tw) \ = \ w^{-1}tw \tag{2.25}$$

But, by the fact that π is a morphism we have that :

$$\pi_{(tw)-1} \ = \ \pi_{w^{-1}t} \ = \ = \pi_{w^{-1}} \circ \pi_t \tag{2.26}$$

Now let's remark that $\forall t \in T$ we have that :

$$\pi_t(t) \ = \ \mathrm{sgn}_t(t) \ ttt \ = \ -t \tag{2.27}$$

Indeed, let's write $t = s_1...s_k s s_k...s_1$ for a k that is minimal. then it is clear that :

$$\{1 \leq l \leq 2k+1 \ : \ t = s_1...s_{l-1}s_l s_{l-1}...s_1\} \ = \ \{k+1\} \tag{2.28}$$

as by the minimality, it can't be true for $l \leq k$ that $t = s_1...s_{l-1}s_l s_{l-1}...s_1$ and as if it is true for some $l = k+1+l'$ with $l' > 0$ we have that

$$t \ = \ s_1 s_2...s_k s s_k...s_{k-l'+1}s_{k-l'}s_{k-l'+1}...s_k s s_k...s_2 s_1 \tag{2.29}$$

Therefore, by multiplying both sides by $s_1 s_2...s_k s$ from the right and by $s s_k...s_2 s_1$ from the left, we obtain that :

$$s \ = \ s_k...s_{k-l'+1}s_{k-l'}s_{k-l'+1}...s_k \tag{2.30}$$

Therefore, by replacing s in t we have that :

$$t \ = \ s_1...s_k s s_k...s_1 \ = \ s_1...s_k s_k...s_{k-l'+1}s_{k-l'}s_{k-l'+1}...s_k s_k...s_1 \ = \ s_1...s_{k-l'}...s_1 \tag{2.31}$$

Which again contradicts the minimality of k. Therefore, the equality (2.28) is verified and we have that :

$$\pi_t(t) \ = \ -t \tag{2.32}$$

And by computing equality (2.26) on t we obtain that :

$$\begin{aligned} \pi_{(tw)^{-1}}(t) \ &= \ \pi_{w^{-1}}\pi_t(t) \\ &= \ \pi_{w^{-1}}(-t) \\ &= \ - \ \pi_{w^{-1}}(t) \\ &= \ -\mathrm{sgn}_{w^{-1}}(t) \ w^{-1}tw \end{aligned} \tag{2.33}$$

And we finally conclude that $\mathrm{sgn}_{w^{-1}}(t) = -1$. $\square$

As a Corollary we have the following lemma :

Lemma 2.16. *The exchange property*
Let (W, S) be a Coxeter system and let $w = s_1 s - 2 ... s_k \in W$ and $t \in T$, then, if $l(tw) < l(w)$ then, there exists some $1 \le l \le k$ such that :

$$tw \;=\; s_1 s_2 ... \hat{s}_l ... s_k \tag{2.34}$$

Proof. By the previous lemma, we know that $\mathrm{sgn}_{w^{-1}} t \;=\; -1$. Therefore, we know there exists a $1 \le l \le k$ such that $tw \;=\; s_1 s_2 ... \hat{s}_l ... s_k$. □

Lemma 2.17. *Let (W, S) be a Coxeter system and let $w = s_1 s_2 ... s_k \in W$, with $k = l(w)$ and let's take $t \in T$. Then, the following are equivalent :*

1. *$l(tw) < l(w)$*
2. *$tw \;=\; s_1 ... \hat{s}_l ... s_1$ for some $1 \le l \le k$*
3. *$t = s_1 ... s_l ... s_1$ for some $1 \le l \le k$*

Moreover, such an l is uniquely determined.

Proof. By Lemma 2.15 we already know that (1) implie (2). Furthermore, the equivalence between (2) and (3) is a tautology. Let us prove that (2) implies (1). Indeed, if $tw \;=\; s_1 ... \hat{s}_l ... s_1$ for some $1 \le l \le k$ then :

$$l(tw) \;\le\; k+1 \;<\; k \;=\; l(w) \tag{2.35}$$

which is (1). It last to show that this l appearing in property (2) and (3) is unique under the hypothesis that $k = l(w)$. Let us define $t_i = s_1 s_2 ... s_i ... s_1$ for all $1 \le i \le k$. Then, we want to show that $t_i \ne t_j$ for every $i \ne j$. Let's reason by absurd and suppose the contrary. Therefore, there exists $i < j$ such that $t_i = t_j$. Then,

$$\begin{aligned} w \;&=\; t_i t_j \; w \\ &=\; t_i s_1 ... \hat{s_j} ... s_k \\ &=\; s_1 ... \hat{s}_i ... \hat{s_j} ... s_k \end{aligned} \tag{2.36}$$

As i was less than j. But this is a contradiction with the exchange property applied for $t = t_i t_j$. Therefore we needed that $t_i \ne t_j$ for every $i \ne j$. In particular l must be unique. □

With all those lemma, we are now ready to prove theorem 2.13.

Proof. Let $w = s_1 s_2 ... s_k$ with $k = l(w)$, then $w^{-1} = s_k ... s_1$ and due to the previous lemma, we know that :

$$\begin{aligned} &\#\{t \in T \;:\; \mathrm{sgn}_{w^{-1}}(t) = -1\} \\ =\; &\#\{t \in T \;:\; t = s_1 ... s_i ... s_k \text{ for some } 1 \le l \le k\} \;=\; k \;= l(w) \end{aligned} \tag{2.37}$$

As every of the $t_i = s_1 ... s_i ... s_1$ are different from each other. □

The following theorem, describe the writing reduction of a world in a Coxeter group when it's not written in one of its minimal writings.

Theorem 2.18. *Deletion property*

Let (W,S) be a Coxeter system and let $w = s_1 s_2 ... s_k$ for some k with $l(w) < k$ then there exists two different indices $1 \leq i < j \leq k$ such that :

$$w = s_1 ... \hat{s_i} ... \hat{s_j} ... s_k \tag{2.38}$$

a consequence is the following proposition :

Proposition 2.19. *Let (W,S) be a Coxeter system and let $w = s_1 ... s_k$ for some $s_i \in S$ then, if $l(w) < k$ there exists a sub-word $s_{i_1} ... s_{i_{l(w)}}$ of $s_1 ... s_k$ such that $w = s_{i_1} ... s_{i_{l(w)}}$.*

This proposition is used in the following :

Proposition 2.20. *Let (W,S) be a Coxeter system, and let's suppose that $w = s_1 s_2 ... s_k = s'_1 s'_2 ... s'_k$ for some $s_i, s'_i \in S$ with $k = l(w)$. Then,*

$$\{s_1, s_2 ... s_k\} = \{s'_1, s'_2 ... s'_k\} \tag{2.39}$$

Remark 2.21. To be precise, the upper equality is an equality of sets an not of multi-sets. Indeed, as a simple example that the multi-sets can be different, we take the Coxeter group S_3 and the permutation $(2,3)(1,2)(2,3) = (1,3) = (1,2)(2,3)(1,2)$ therefore, we have the multi-sets :

$$\{(2,3),(1,2),(2,3)\} \quad \text{and} \quad \{(1,2),(2,3),(1,2)\} \tag{2.40}$$

Proof. Suppose that the two sets are not equal. Therefore, there exists an $1 \leq i \leq k$ minimal such that $s_i \notin \{s'_1, s'_2 ... s'_k\}$. Furthermore, by lemma **??** we know that :

$$\begin{aligned} \{s'_1 ... s'_j ... s'_1 : j = 1,2,...,k\} &= \{t \in T \ : \ l(tw) < l(w)\} \\ &= \{s_1 ... s_j ... s_1 : j = 1,2,...,k\} \end{aligned} \tag{2.41}$$

As those sets are equal, there must be an index $1 \leq j \leq k$ such that for our previous i we have :

$$s_1 ... s_i ... s_1 = s'_1 ... s'_j ... s'_1 \tag{2.42}$$

In particular, by previous proposition, there exists a sub-word of the right hand side which is of size 1 and which is equal to $s_i \in W$. Therefore, either s_i is one of the previous $s_1 ... s_{i-1}$ which would be a contradiction with the minimality of i, or s_i is one of the $s'_1, ..., s'_j$ which is a contradiction with our choice of i. Therefore, the two sets must be the same.

Warnig: hypothesis reduced in the exchange property!

Theorem 2.22 (Matsumoto). *Let W be a group and $S \subset W$ a finite subset of generators of W of order 2. Then the following assertions are equivalent:*

- *(i) (W, S) is a Coxeter system.*
- *(ii) (W, S) satisfies the exchange property.*
- *(iii) (W, S) satisfies the deletion property.*

Proof. $(i) \Rightarrow (ii)$. This implication has already been shown above.

$(ii) \Rightarrow (iii)$. Let $w = s_1 \dots s_k$ such that $\ell(w) < k$. Let i be maximal such that $s_i s_{i+1} \dots s_k$ is not reduced (i.e. $s_{i+1} \dots s_k$ is reduced). We have $\ell(s_i s_{i+1} \dots s_k) \leq k - i = \ell(s_{i+1} \dots s_k)$. Now, using exchange property, we obtain $s_i s_{i+1} \dots s_k = s_{i+1} \dots \hat{s}_j \dots s_k$ for some $i + 1 \leq j \leq k$. Therefore, $w = s_1 \dots s_{i-1} s_i s_{i+1} \dots s_k = s_1 \dots s_{i-1} \hat{s}_i s_{i+1} \dots \hat{s}_j \dots s_k$ and we have the result (let us note that this implication remains true for weaker hypothesis since we did not use the fact that S is of order 2).

$(iii) \Rightarrow (ii)$. Let $w = s_1 \dots s_k$, $k = \ell(w)$, $s \in S$, such that $\ell(sw) = \ell(ss_1 \dots s_k) \leq \ell(w) = \ell(s_1 \dots s_k) = k$. So $ss_1 \dots s_k$ is not reduced. We can apply the deletion property. Suppose that $sw = ss_1 \dots \hat{s}_i \dots \hat{s}_j \dots s_k$ (but $\ell(sw) \leq k - 1 < l(w)$). So $ssw = sss_i \dots \hat{s}_i \dots \hat{s}_j \dots s_k$. This leads to $\ell(s_1 \dots \dots \hat{s}_i \dots \hat{s}_j \dots s_k) < k$, which is a contradiction, so this case has to be excluded. Hence, we have $sw = \hat{s} s_1 \dots \hat{s}_i \dots s_k$.

$(ii) \Rightarrow (i)$. Using $(ii) \Rightarrow (iii)$, we can assume both (ii) and (iii). Define $m(s, s') =$ order of ss' in W, for all $s, s' \in S$. Let $(\tilde{W}, S)$ be the Coxeter group associated to m. Clearly, $\phi : \tilde{W} \mapsto W, s \to s$ is a surjective homomorphism. We need to show that ϕ is also injective. Let $s_1 \dots s_m = e$ in W. By the deletion property, m is even, say $m = 2k$. So we can write our relation on the form

$$s_1 \dots s_k = s'_1 \dots s'_k \tag{2.43}$$

where $s'_1 = s_{2k}, \dots s'_k = s_{k+1}$. We must now prove that (2.43) is a consequence of the pairwise relations $(ss')^{m(s,s')} = e$. The proof is done by induction on k, the case $k = 1$ being trivially correct.

- Case 1: Suppose $w := s_1 \dots s_k$ is not reduced. By deletion property, there exists a position $1 \leq i < k$ such that $s_{i+1} s_{i+2} \dots s_k$ is reduced but $s_i s_{i+1} s_{i+2} ... s_k$ is not. By the exchange property, we then have that $s_{i+1} s_{i+2} \dots s_k = s_i s_{i+1} \dots \hat{s}_j \dots s_k$ for some $i < j \leq k$. This relation is of length $< 2k$ and hence fine. Plugging this result into (2.43) gives $s_1 \dots s_i s_i s_{i+1} \dots \hat{s}_j \dots s_k = s'_1 s'_2 \dots s'_k$. The factor $s_i s_i$ can be deleted, leaving a relation of length $< 2k$. Hence the relation (2.43) is fine.
- Case 2: Suppose $w = s_1 \dots s_k$ is reduced, $k = \ell(w)$. We can assume that $s_1 \neq s'_1$ (otherwise the relation (2.43) is equivalent to a shorter relation). We have $\ell(s'_1 s_1 s_2 \dots s_k) = \ell(s'_1 s'_1 s'_2 \dots s'_k) = \ell(s'_2 \dots s'_k) \leq k - 1 < \ell(s_1 \dots s_k)$. Using exchange property, we have $s'_1 s_1 \dots s_k = s_1 \dots \hat{s}_i \dots s_k$ for some i. Hence, $s_1 \dots \hat{s}_i \dots s_k = s'_2 \dots s'_k$.
  If $i < k$, then $s'_1 s_1 s_2 \dots s_{k-1} = s_1 \dots \hat{s}_i \dots s_{k-1}$. So $s'_1 s_1 s_2 \dots s_{k-1} s_k = s_1 \dots \hat{s}_i \dots s_{k-1} s_k$. Hence, $s'_1 s_1 \dots s_k = s'_2 \dots s_k$ is a consequence of Coxeter relations.

If $i = k$, we have to work a little bit harder. We have $s_1' s_1 \dots s_{k-1} = s_1' s_2' \dots s_k'$. Thus it will suffice to show that $s_1 s_1 \dots s_{k-1} = s_1 s_2 \dots s_k$ is a consequence of Coxeter relations. Applying recursively the rule, we have $s_1 s_1' s_1 \dots s_{k-2} = s_1' s_1 \dots s_{k-1} \Rightarrow s_1' s_1 s_1' s_1 \dots s_{k-3} = s_1 s_1' s_1 \dots s_{k-2}$ $\Rightarrow \dots$ Thus in the end, the question will be reduced to the relation $s_1 s_1' s_1 s_1' \dots = s_1' s_1 s_1' s_1 \dots$, which is of course a consequence of the Coxeter relation $(s_1 s_1')^{m(s,s')} = e$.

Example 2.23. The group S_n can be generated by transpositions, which are order 2 elements. Using the above theorem, we conclude that S_n is actually a Coxeter group.

2.2 Geometric representation

Let (W, S) be a Coxeter system, $S = \{s_1, \dots s_n\}$, m the associated Coxeter matrix. We write $m_{ij} = m(s_i, s_j)$. Let V be a $\mathbb{R}$-vector space of dimension n, with a basis $\alpha_1, \dots, \alpha_n$. We consider the symmetric bilinear map

$$\langle \cdot, \cdot \rangle : V \times V \mapsto \mathbb{R} \tag{2.44}$$

defined through

$$\langle \alpha_i, \alpha_j \rangle = \begin{cases} -\cos\left(\frac{\pi}{m_{ij}}\right) & \text{if } m_{ij} < +\infty \\ -1 & \text{if } m_{ij} = +\infty \end{cases} \tag{2.45}$$

Not that $\langle \cdot, \cdot \rangle$ is not positive definite in general.

Proposition 2.24. *The following map extends to a homomorphism:*

$$W \mapsto GL(V), s_i \to \sigma_i \tag{2.46}$$

where $\sigma_i : v \to v - 2\langle v, \alpha_i \rangle \alpha_i$.

Remark 2.25. We have $\sigma_i(\alpha_i) = \alpha_i - 2\langle \alpha_i, \alpha_i \rangle \alpha_i = -\alpha_i$. Thus, if $v \in V$ is such that $\langle v, \alpha_i \rangle = 0$, then $\sigma_i(v) = v$. Therefore, if $\langle \cdot, \cdot \rangle$ was positive definite, σ_i would be interpreted as a reflexion through the hyperplane orthogonal to α_i.

Proof. First, let us show that σ_i is invertible for all i. We have $\sigma_i^2(v) = \sigma_i(v) - 2\langle v, \alpha_i \rangle \sigma_i(\alpha_i) = v - 2\langle v, \alpha_i \rangle \alpha_i + 2\langle v, \alpha_i \rangle \alpha_i = v$.

Now, let us show that $(\sigma_i \sigma_j)^{m_{ij}} = Id_V$. For $i \neq j$, define $V_{ij} = \mathrm{Span}_{\mathbb{R}}(\{\alpha_i, \alpha_j\})$. Furthermore, $V_{ij}^{\perp} = \{v \in V | \langle v, \alpha_i \rangle = 0, \langle v, \alpha_j \rangle = 0\}$. Before proceeding, we show the following lemma:

Lemma 2.26. $V = V_{ij} \oplus V_{ij}^{\perp}$ *if* $m_{ij} < +\infty$.

Proof. Let $v \in V$. We want to find $\lambda_i, \lambda_j \in \mathbb{R}$ such that $\tilde{v} = \lambda_i \alpha_i + \lambda_j \alpha_j \in V_{ij}$ and $v - \tilde{v} \in V_{ij}^{\perp}$. We have

$$\begin{aligned} \langle \tilde{v}, \alpha_i \rangle &= \lambda_i \langle \alpha_i, \alpha_i \rangle + \lambda_j \langle \alpha_i, \alpha_j \rangle \\ &= \lambda_i + C\lambda_j \end{aligned} \tag{2.47}$$

where $C = \langle \alpha_i, \alpha_j \rangle = -\cos\left(\frac{\pi}{m_{ij}}\right)$. Furthermore,

$$\langle \tilde{v}, \alpha_j \rangle = \lambda_i C + \lambda_j \tag{2.48}$$

Since

$$\det \begin{pmatrix} 1 & C \\ C & 1 \end{pmatrix} = 1 - C^2 = 1 - \cos^2\left(\frac{\pi}{m_{ij}}\right) \neq 0, \tag{2.49}$$

if $m_{ij} < +\infty$. Therefore, we can find unique λ_i and λ_j such that

$$\langle \tilde{v}, \alpha_i \rangle = \langle v, \alpha_i \rangle \quad \text{and} \quad \langle \tilde{v}, \alpha_j \rangle = \langle v, \alpha_j \rangle \tag{2.50}$$

Now let us come back to the proof of the proposition. Using the lemma, we have $v = \tilde{v} + (v - \tilde{v})$ such that $\langle v - \tilde{v}, \alpha_i \rangle = 0 = \langle v - \tilde{v}, \alpha_j \rangle = 0$. Hence $\sigma_i(v - \tilde{v}) = v - \tilde{v} - 2\langle v - \tilde{v}, \alpha_i \rangle \alpha_i = v - \tilde{v}$ and $\sigma_j(v - \tilde{v}) = v - \tilde{v}$. In the basis $\{\alpha_i, \alpha_j\}$ of V_{ij}, the matrix associated to σ_i is given by

$$\begin{pmatrix} -1 & -2C \\ 0 & 1 \end{pmatrix} \tag{2.51}$$

In fact, we have $\sigma_i(\alpha_i) = -\alpha_i$ and $\sigma_j(\alpha_j) = \alpha_j - 2C\alpha_i$. Similarly, the matrix associated to σ_j is given by

$$\begin{pmatrix} 1 & 0 \\ -2C & -1 \end{pmatrix} \tag{2.52}$$

Therefore,

$$(\sigma_i)(\sigma_j) = \begin{pmatrix} -1 & -2C \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ -2C & -1 \end{pmatrix} = \begin{pmatrix} -1 + 4C^2 & 2C \\ -2C & -1 \end{pmatrix} \tag{2.53}$$

The characteristic polynomial P of this matrix is given by $P(t) = t^2 - (-2 + 4C^2)t + 1$.The roots are given by $t_{\pm} = \cos\left(\frac{2\pi}{m_{ij}}\right) \pm i \sin\left(\frac{2\pi}{m_{ij}}\right)$. This characterizes a rotation of $2\pi/m_{ij}$. So, the order of $\sigma_i \sigma_j$ is given by m_{ij}.
